

Introduction to the Open Service Broker API

Doug Davis | IBM

dug@us.ibm.com | @duginabox

A Brief History...

CLOUD FOUNDRY

- ▶ PaaS with a mission to make managing Cloud apps simple

```
$ cf push myapp
```

```
$ cf scale myapp -i 5
```

- ▶ CF manages deployment, orchestration, routing ...
- ▶ Let's developers focus on coding, not infrastructure

Applications are not islands

- ▶ Often applications leverage ancillary "Services"
 - ▶ E.g. Application stores data in database
- ▶ Critical to application's success
 - ▶ But developers shouldn't spend their time managing them

Managing Services Can Be A Challenge

- ▶ Creating and managing services is non-trivial
 - ▶ Duplication of effort across teams, or
 - ▶ Ops team manages it for you on **their** schedule
 - ▶ Managing credentials could be problematic
 - ▶ Sent via email, sticky-notes, etc...
 - ▶ Where are they stored? Plain text in config files?
- ▶ CF shifts the burden to the Platform via self-service model
 - ▶ "Tell us what you need and we'll manage it for you"
 - ▶ Service Credentials are protected and provided at runtime

User's Perspective

- ▶ Easy user experience

```
$ cf create-service mysql free myDB
```

```
$ cf bind-service myApp myDB
```

- ▶ Credentials are made available to "myApp" via an env var

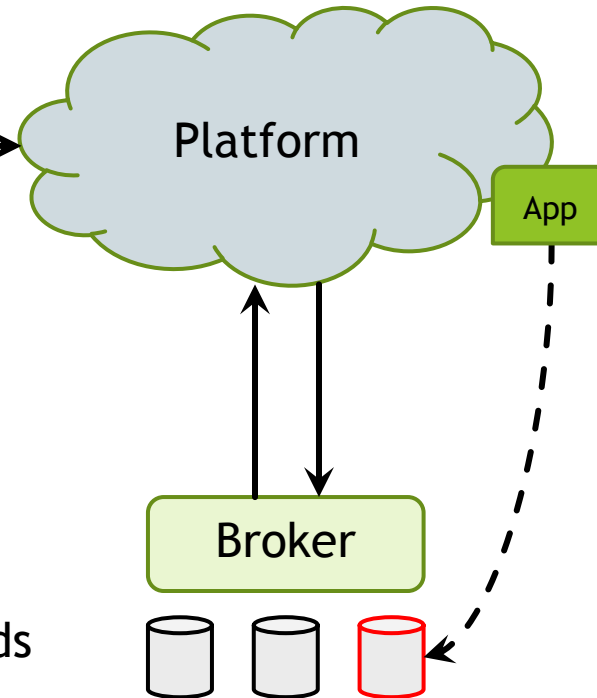

```
VCAP_SERVICE = {  
  "mysql": [{  
    "credentials":  
      "username": "fd7d1b58", "password": "c07750d55",  
      "host": "fd7d1b58.db-svc.com", "port": 443, ...  
    }]  
}
```

The Magic

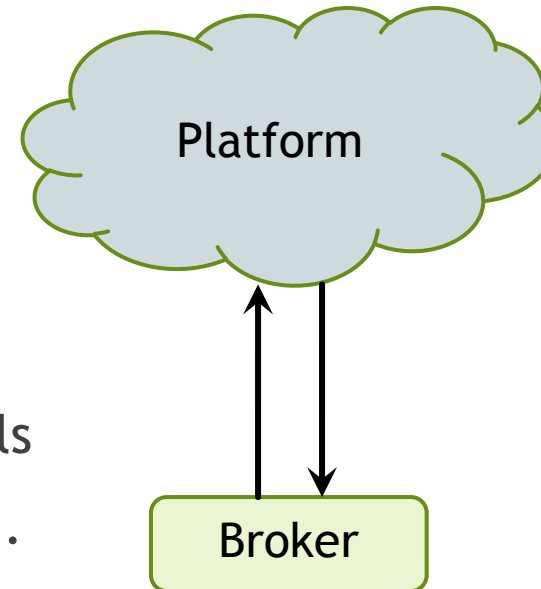

1. Register Service Broker
2. Retrieve the Catalog of Services
3. Create a new Service Instance
 - Platform asks Brokers for Instance
4. Deploy Application
5. Bind Instance to an Application
 - Platforms asks for new Binding/Creds
6. Access Service from Application
 - Using Creds from Binding
 - VCAP_SERVICES env var

Cloud Foundry Service Broker API

- ▶ API between the Platform and a Service Broker
- ▶ Abstracts the Service Lifecycle APIs
- ▶ Service Brokers
 - ▶ Manage all aspects of Service's lifecycle
 - ▶ User Initiated: Create, Delete, Provide Credentials
 - ▶ Automatic: Auto-Scale, Backup, Recovery, QoS, ...
 - ▶ Hosted anywhere - in or out of the Platform
 - ▶ Application is usually unaware

What is a Service?

- ▶ A service can be just about anything
- ▶ Data & Analytics - e.g. DBs, ElasticSearch
- ▶ Integration - e.g. Box, Twitter, SendGrid
- ▶ Utilities - e.g. conversions, speech to text
- ▶ Infrastructure - networks, volumes, routing
- ▶ DevOps - monitoring, metrics, auto-scaling

Why?

▶ Application Developers / Managers

- ▶ Can focus on their business logic
- ▶ Services managed by the experts
- ▶ Self-service model speeds up CI/CD timelines

▶ Service Providers

- ▶ Low barrier or entry for new Service Providers
- ▶ Interop: easily integrated into environments that supports the API
- ▶ With ease of access to services, an increase in their usage (\$)

Open Service Broker API

- ▶ CFF donated SB API to the Open Service Broker API Project
- ▶ OSB API Project
 - ▶ Evolve API into a community specification
 - ▶ To promote **interoperability** across Cloud Platforms (beyond CF)
 - ▶ Cloud Foundry, Kubernetes, OpenShift
 - ▶ Support of key Cloud leaders:
 - ▶ Fujitsu, Google, IBM, Pivotal, RedHat and SAP

OSB API - Looking Forward

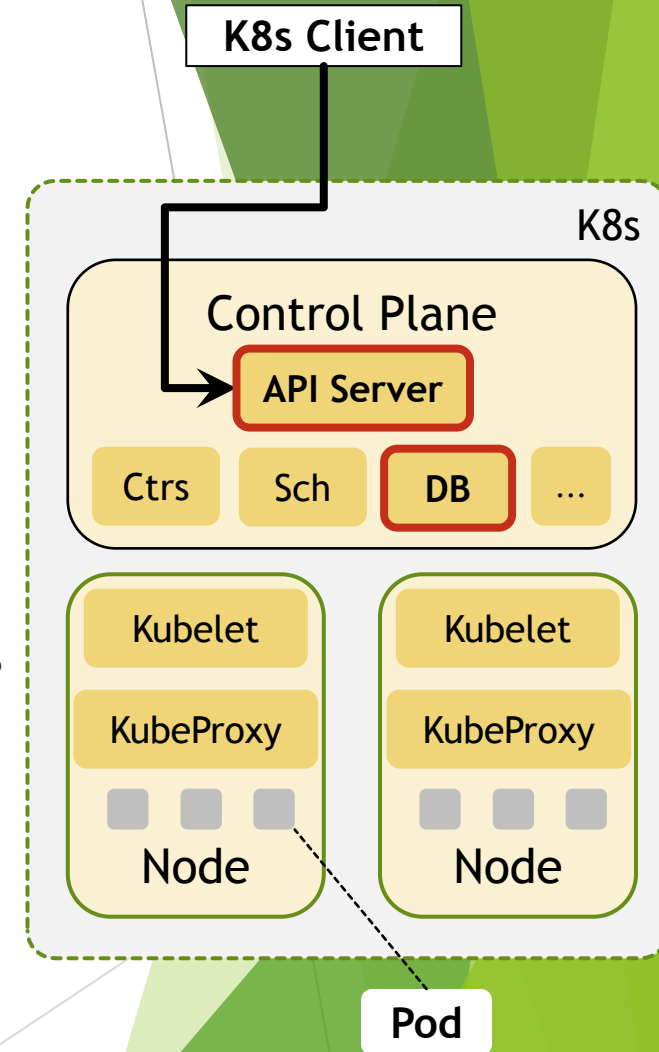

- ▶ Removing CF specifics in the spec
 - ▶ Org, space to be replaced with "context"
 - ▶ Define a Context Profile for each Platform
- ▶ Parameter Schemas
 - ▶ To define the shape of the "parameters"
 - ▶ Enables more advanced UI/presentation
- ▶ Enable additional Auth mechanisms
 - ▶ Beyond Basic Auth

OSB API - Looking Forward - Part Deux

- ▶ Define additional Service Lifecycle Actions
 - ▶ E.g. Backup/restore for DBs
 - ▶ Allow for Service specific extensions
- ▶ Allow for a more RESTful model - e.g. GET
- ▶ Allow all operations to be asynchronous
- ▶ Originating Identity

Kubernetes in a minute!

- ▶ Container Orchestration
- ▶ A DB with an asynchronous HTTP/REST front-end
 - ▶ User is exposed to all of the resources in the model
- ▶ A set of watchers that act as resources change
 - ▶ Controllers react to CRUD operations to manage the resources
 - ▶ Schedulers watch to make sure desired state == action state
 - ▶ Workers/Kubelet watch for new Pods to be deployed on their Nodes
- ▶ Pod: set of containers that must be co-located on same Node
- ▶ Labels: filtering/searching mechanism
- ▶ KubeProxy to manage intra-cluster communications

Kubernetes: Extend the Resource Model

▶ New OSB API specific resources

- ▶ Broker

- ▶ ServiceClass

"service" was already taken / "Plan" is nested

- ▶ Instance

- ▶ Binding

Credentials stored in Secrets in "core"

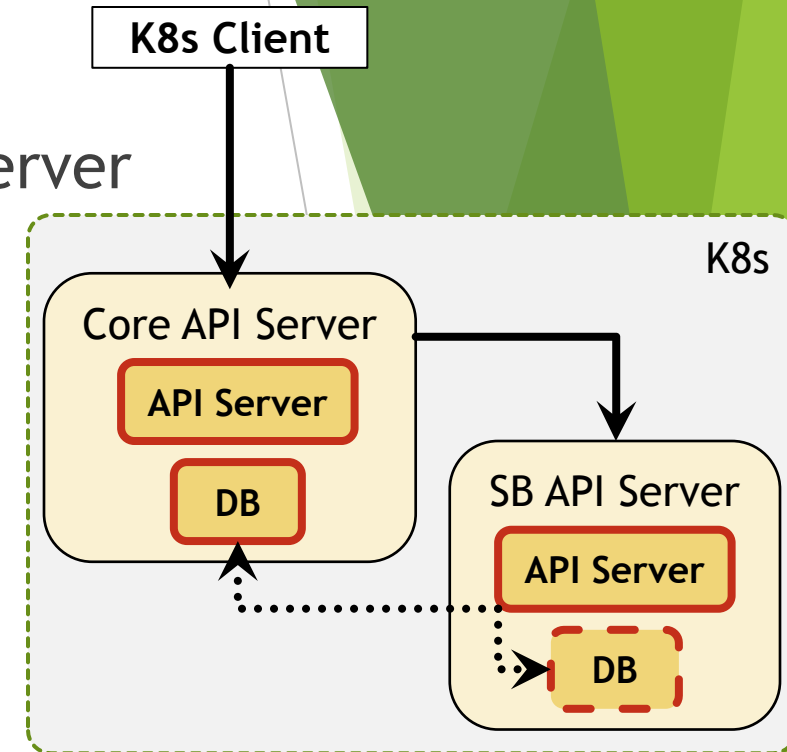

▶ New "core" resource

- ▶ PodPreSet

Auto-injects new Pods with credentials.
Defined as part of the Binding resource

Kubernetes: New API Server

- ▶ Since not part of "core" we needed a separate API Server
 - ▶ Basically a mini-Kubernetes
 - ▶ Accessed via API aggregation
 - ▶ Can use the "core" API Server's DB or its own
- ▶ Our work has been on the bleeding-edge
 - ▶ API Server: first to actually create a new one
 - ▶ API Aggregation: to share a single endpoint across API Servers
 - ▶ PodPreset

Kubernetes: User Experience

- ▶ Can work with resources directly

```
$ kubectl create -f broker.yaml           # Admin action
$ kubectl create -f instance.yaml        # Dev action
$ kubectl create -f binding.yaml         # Dev action
```

- ▶ Or, kubectl plugin for better UX

```
$ kubectl create-service-instance SERVICE_CLASS_NAME \
    PLAN_NAME NAMESPACE INSTANCE_NAME
$ kubectl bind-service-instance INSTANCE_NAME \
    BINDING_NAME NAMESPACE
```

Kubernetes: Support for OSB API - Status

- ▶ Incubator project/SIG: Service Catalog
- ▶ Will be fully OSB API specification compliant
- ▶ Very involved in the OSB API WG
 - ▶ Via IBM, RedHat and Google's participation
- ▶ Currently in 'alpha' but 'beta' will be soon
 - ▶ Beta implies backwards compatible from then on
 - ▶ So its relatively safe for enterprises to pick-up and play with

Get Involved

- ▶ Web Site: <https://www.openservicebrokerapi.org/>
